

SDWAN-Notes

The design includes two Validators and three Controllers to provide a resilient SD-WAN control plane. Both Validators are registered in DNS, allowing WAN Edge devices to dynamically resolve and connect to an available Validator. The Validators maintain and update the orchestration database, ensuring that orchestration information remains available across the deployment. If one Validator becomes unavailable, the secondary Validator can continue to provide orchestration services, provided network connectivity and DNS resolution remain operational. This eliminates a single point of failure and ensures continued controller discovery and authentication for the SD-WAN fabric. The three Controllers further enhance resilience by maintaining control-plane availability, allowing the fabric to continue operating even in the event of an individual controller failure. As long as connectivity exists between the WAN Edge devices, Validators, and Controllers, the SD-WAN environment can continue to function without service interruption.

After installation, a short period should be allowed for the CA server, routers, validators and controllers to synchronise. During this time, certificates are validated, DNS records are resolved, and orchestration data is replicated across the platform to ensure a resilient and fully operational SD-WAN control plane.
